

Characterizing the mechanisms of altered gaze processing in psychosis & bipolar disorder using drift diffusion modeling & EEG

Carly A. Lasagna, Ivy F. Tso, Timothy J. Pleskac

“ Processing of social information – like **eye gaze** – is disrupted in schizophrenia and bipolar disorder, contributing to poor functional outcomes. But the latent **mechanisms are poorly understood**, impeding the design of targeted interventions.

The Present Study

$N = 100$ with schizophrenia (SZ), bipolar disorder (BD), or controls (HC)

Neural Correlates of Decision Processes:

Stimuli:

Direct

Indirect

Task:

“looking at me?” (y/n)

EEG:

TF Analysis

Stim-evoked power:

Theta
4-8Hz

Alpha
8-12Hz

Beta
13-30Hz

Gamma
30-50Hz

Latent Decision Processes:

RTs & Choices:
Hierarchical
Bayesian Drift
Diffusion Model
(DDM)

Ratcliffe, 1978

DDM Results

SZ and BD accumulated evidence less efficiently than HC for indirect gaze

SZ had \uparrow response caution than BD and HC

EEG Results

Theta power:

A) ↓ in SZ and BD

Grove et al 2020, Lasagna et al 2023

B) ↑ theta related to ↑ efficiency of evidence accumulation

Beta suppression:

A) ↓ in SZ

Grove et al 2020

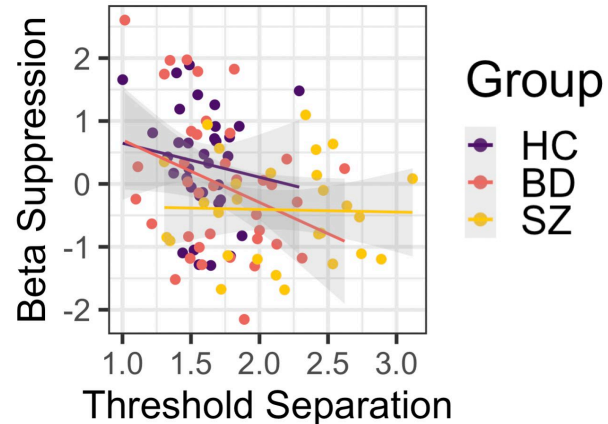

B) ↑ beta power suppression related to ↓ response caution

A) Group Diffs: Beta Suppression

B) Correlations: Beta Suppression & Threshold Separation

Rho = -0.30, $p = .003$

Conclusions

It is possible that altered **evidence accumulation/theta power in SZ and BD** and altered **response caution/beta power in SZ** are each jointly signaling a common underlying abnormality. Future work will examine/model this directly.

Thank you
